Like all good girls I have been using this website for quite some time now but I rarely have access to a computer which is why I decided to sign up for an account which is what you are looking at right now. That's why you see my name which is all that I should be sharing with the world. The subject matter disclosed herein relates to gas turbine engines and, more particularly, to gas turbine engines having a reduced static pressure spool. Modern gas turbine engines are designed to operate at increasingly high temperatures. As a result, engine components such as airfoils, rotor blades, buckets and vanes experience thermal stresses. Under certain engine operating conditions, these thermal stresses may lead to material failure. For example, components formed of alloys such as nickel-based superalloys may suffer from microcracking during high temperature service. Microcracking is the formation of cracks generally less than about 0.1 inch in length. To improve the service life of gas turbine engine components, engine systems are often cooled with air bled from the compressor. As the temperature of the primary gas path flow is increased, cooling air routed through the component extracts heat from the component and may reduce the overall temperature of the component. Additionally, the aerodynamic surface of the gas turbine engine components undergo significant temperature changes. The pressure distributions and overall shape of the component generally do not change appreciably during rotation. The airfoil shape, however, is changed when the airfoil experiences a pitch change during rotation. Accordingly, the component includes a surface generally known as a fuselage which corresponds to the shape of the outer surface of the airfoil. Many current airfoils have a fuselage on the pressure side or suction side of the airfoil. Fuselage structures increase the cost and weight of a component. However, a pressure side fuselage may be
